Proper Motion of Barnards Star

Florian Freistetter, ZAH, Heidelberg
florian@ari.uni-heidelberg.de
Stars do move!

Even if the stars are called „fixed stars“ sometime, they are not really fixed. This word was chosen in ancient times, when one did not know much about the real nature of the celestial bodies. To distinguish them from the „moving stars“, that change their position every night. Today we know, that those are planets and that also the „fixed“ stars do move – although their motion is very small and it took some time for the astronomers to measure it.

There are different reasons why a star changes its position on the sky. There are apparent changes, due to the motion of the Earth around the Sun (parallax) and due to the finite velocity of light (aberration). And there is also a real change of position, due to the proper motion of the star.

A star, moving on the sky, is changing its right ascencion and declination. The following formula gives the change during a certain time:

\[
\mu_\delta = \mu \cos(\theta)
\]
\[
\mu_\alpha = \mu \frac{\sin(\theta)}{\cos(\theta)}
\]

The total proper motion per time unit is called \(\mu\); \(\theta\) is the angle, in which the star is moving (North = 0°).

How fast is Barnards Star

The star with the fastest proper motion measured so far is Barnards Star. How fast it really is, can be found out with Aladin:

We start Aladin and then switch to undergraduate mode:

*edit → user preferences → profile → undergraduate*

Restart Aladin to validate the new configuration.

Open the server selector

*File -> Open*

Switch to tab „Aladin images“, enter „Barnard Star“ in the „target“ field and hit „submit“.

The available pictures of Barnards Star are listed. To investigate the proper motion, we chose two picture, that were made at different times. The longer in between, the better. Let's choose two images from the POSSII-Catalogue (13’ x 13’). The column „date“ shows when the pictures were made. We take the images from 1991 and 1988.

*Bild 1: Chosing the pictures of Barnards Star*

Klick on „Submit“ to load the pictures in Aladin.

We now can combine the two images to a movie and see if the star has moved. Therefore we use the „blink“ function:

*image → blink / movie generator*

We specify the images we want to use and hit „create“:
To measure how far the star has moved, we use the “rgb” function:

\[ \text{image} \rightarrow \text{RGB} \]

This function is meant to use for the combination of images in different wavelengths to obtain a color picture. But we can use also for our case.

In the “rgb”-window, we chose one of the images for the red channel and one for the green. Klicking „create” gives a new image.

The two images are now superomposed. Where the stars have not moved, they appear white. But Barnards Star has moved and thus we see two images: one in green and one in red:

We now magnify the part of the image around the Barnard Star („zoom“) and use the „dist“-tool to measure the distance between the red and the green image. The result will be approx. 32 arc seconds: that is the apparent distance that the star has moved.

But during what time? With a right-click on the images in the Aladin-stack, we can view the properties of the image. There we find the exact time, when the pictures were made:

We can now easily calculate the time that has passed during the two exposures: 3.0935182751 years.

Thus, the proper motion per year for Barnards star is \(10.35\) arcseconds/year!
Further Analysis

If the star moves 10.35 arcseconds per year along the celestial sphere, what is its real velocity through space? To calculate this value, we have to know the distance of Barnard’s Star.

To obtain this information, we load a catalogue: File -> Load catalogue -> Simbad Database

The catalogues symbol is now displayed in the stack on the right side. With the “mark”-tool we select the objects of the catalogue in the image and the database entries are shown in the measurement window:

Barnard’s Star is here listed under its other name: “V* V2500 Oph” (“V” means “variable” since Barnard’s Star is a variable star). Kicking on its name opens the Simbad-Database in the webbrowser where one can find all relevant data:

*Parallaxes mas* indicates the parallax of the star in milliarcseconds (mas). It is given as 0.549 arcseconds.

We now can calculate easily the distance $r$ to Barnard’s Star:

$$ r = \frac{1}{0.549} = 1.82 \text{ pc} $$

We now known, that Barnard’s Star is 1.82 parsecs away and shows an apparent motion of 10.35 arcseconds per year.

Simple trigonometry gives the real distance, that Barnard’s Star covers in a year:

The distance $X$ that the star moves during a year is 0.0000912 parsec or 2813000000 km. That corresponds to a tangential velocity of $90 \text{ km/s}$ or $321000 \text{ km/h}$.
Motion on the celestial sphere

The visible motion of Barnard's Star on the sky is also influenced by other factors: the motion of the earth around the sun; the influence of the moon on the motion of the earth, etc.

The APFS-toll of the german virtual observatory (GAVO) allows a visualisation of the real motion of a star on the celestial sphere. It can be accessed at [http://dc.zah.uni-heidelberg.de/apfs/res/apfs_new/hipquery/form](http://dc.zah.uni-heidelberg.de/apfs/res/apfs_new/hipquery/form).

Enter „Barnard Star“ in the „Object“ field and specify the timescale. Let's look at the motion between June 1st 2009 and June 1st 2014. The output interval („interval of generation“) should be 24 hours. As „output format“ we choose a graphical representation and select „VOPlot“.

We can now see how the position of the star is changing during time. There are five loops that correspond to the five years from 2009 to 2014 and are due to the motion of the earth around the sun. The superimposed linear motion from the lower left to the upper right is the real proper motion of the star:

![Bild 9: Motion of Barnard's Star](image)

That gets more clear, if we change the output interval from 24 hours to 8766 hours (one year). The motion of the earth is now filtered out and we can see the linear proper motion of Barnard's Star:

![Bild 10: Motion of Barnard's Star](image)

There we have to adjust the correct columns for „x“ and „y“. We want to have the right ascension („raCIO“) at „x“ and the declination („dec“) at „y“. A click on „plot“ draws the new image.
